Reshape a Table

Stack Tables

Join Tables

- ► Reshape (long <-> wide) with pivot_longer and pivot_wider
- Stack tables by row or by column with bind_rows and bind_cols (or, alternatively, cbind and rbind)
- ► Merge two tables with inner_join, full_join, left_join, right_join, semi_join, and anti_join
- ► Save your outputs

Example: The V-Dem Data

```
library(tidyverse)
d <- read csv(" DataPublic /vdem/1984 2022/vdem 1984 2022 external.csv")
d \gg print(n = 3)
## # A tibble: 6,789 x 211

- **For data cleaning:** Sometime it is much easier to clean the data after reshaping
- For data visualization: Some data visualization functions only take tables shaped in a specific way
- **For data sharing:** Sometimes you want to export the data for human readers (e.g., data coding/labeling)

"But I am sure Excel can do the same thing!" It can do it for HUGE data reliably and fast. And the process is replicable.

Reshape a Table

Stack Tables

OIII Tables

- Let's say we want to merge your GDP data d_gdp with some additional datasets that you know you can just safely stack together.
- Example
 - ▶ Merge with GDP data from 1906 to 1983
 - ▶ Merge with education and Freedom House data from 1984 to 2022

To demonstrate how to stack data vertically, I make a table with GDP data from two previous time periods (1945 to 1983 and 1906-1944).

```
d gdp 1945 <-
 read csv(" DataPublic /vdem/1945 1983/vdem 1945 1983 external.csv") |>
  select(country text id, year, e gdp, e gdppc) |>
 rename("gdp" = "e_gdp", "gdppc" = "e_gdppc")
d gdp 1906 <-
 read_csv("_DataPublic_/vdem/1906_1944/vdem_1906_1944_external.csv") |>
  select(country_text_id, year, e_gdp, e_gdppc) |>
 rename("gdp" = "e_gdp", "gdppc" = "e_gdppc")
d gdp 1945 \mid> print(n = 2)
## # A tibble: 6.082 x 4
##
    country_text_id year gdp gdppc
    <chr> <dbl> <dbl> <dbl> <dbl>
##
## 1 MEX 1945 7827. 3.08
                 1946 8331. 3.17
## 2 MEX
## # i 6.080 more rows
```

Understand the behavior of different join functions

- ▶ left_join: Merge and only keep observations that appear in the left-hand-side table.
- right join: Merge and only keep observations that appear in the right-hand-side table.
- inner join: Merge and only keep observations that appear in both tables.
- ▶ full join: Merge and keep observations that appear either table.
- ▶ anti_join: Filter out observations that does appears in the right-hand-side table
- semi join: Filter out observations that does not appear in the right-hand-side table

are kept in your final merged data.

Some advice based on personal experience

Joining tables is also error-prone.

▶ Add suffixes or prefixes indicating data sources

▶ Failing to do so can cause difficulty with replication.

Add binary indicators (1/0) indicating from in which dataset is each observation available

▶ You want to have a clear mind about which variables from which datasets

2002 148549. 1 13.6

3 MEX

i 6.786 more rows

Add binary indicators about data availability in each sources.

Join Tables

.

Save Outputs

```
What can you do with these binary indicators? We can know the overlaps of multiple sources.

d_fj_habit |>
```

```
## # A tibble: 3 x 3
## # Groups: source_vdem, source_wb [3]
## source_vdem source_wb n
## <dbl> <dbl> <int>
```

group by(source vdem, source wb) |>

1 1 1951 ## 2 1 NA 2148 ## 3 NA 1 2690

If the overlap looks weird to you, you will know that you need to re-examine the data merging process.

Good Habit: Add Availability Indicators

Question: Why not just check ${\tt NA}$ in each variables?

Answer: An observation can be missing for two reasons

- ▶ It is in the one of the tables but it does not contain a value.
- ▶ It is not in any of the tables at all.

 ${\tt join_}$ make it hard to distinguish between the two scenarios.

Data Wrangling (3)

Haohan Chen

Setup

Reshape a Pable

Stack lables

oin Tables

You can save your clean data in a variety of formats. I will highlight two most popular options

- ▶ .csv "comma-separated values," readable by Excel or a text editor
- ▶ .rds "R data serialization," readable by R only

```
# Save to a .csv file
write_csv(d_gdp_1945_2022, "Lec_06/2_data_wrangling_3/data/gdp_1945_2002.csv")
# Save to a .rds file
saveRDS(d_gdp_1945_2022, "Lec_06/2_data_wrangling_3/data/gdp_1945_2002.rds")
```

respectively

You can re-load saved .csv and .rds files using read csv and readRDS

Γable

oin Tables

```
# Read a .csv file
d read 1 <- read csv("Lec 06/2 data wrangling 3/data/gdp 1945 2002.csv")
## Rows: 12871 Columns: 4
## -- Column specification -----
## Delimiter: "."
## chr (1): country text id
## dbl (3): year, gdp, gdppc
##
## i Use `spec()` to retrieve the full column specification for this data.
## i Specify the column types or set `show col types = FALSE` to quiet this message.
# Read a .rds file
d_read_2 <- readRDS("Lec_06/2_data_wrangling_3/data/gdp_1945_2002.rds")</pre>
```

Saving Your Outputs after Data Wrangling

Comparing the two output types

Type	Pro		Con
.csv	*	Readable outside R Conveniently convertible to Excel files	 Variable types may change when you read it back if you do not carefully specify them Error-prone with text data (encoding, line breaks etc.) (Maybe) takes longer to read
.rds	•	 Replicable: Get precisely how the data are saved Smaller files (if stick with default compression) (Sometimes) faster read/write 	Can't read .rds outside R
	•

in Tables

Saving Your Outputs after Data Wrangling

- ► When to save as .csv
 - Simple data types
 - ▶ Want to manually examine it outside R (e.g., Excel)
 - ▶ Want to share it with non-R users
- ▶ When to save as .rds
 - ► Complex combination of data types
 - ► Simply saving for your future use in R
 - Large dataset and you want to save space
 - ► Text data

If you don't care about looking at the data outside R, .rds is a safer option.
